This paper

- Spatial sorting by income
  - Compensating differentials for environmental risk
- Adaptation policy faces a trade-off
  - Protecting risky areas reduces inequality in exposure
  - But also reduces housing affordability
- Today: theory and data from Indian cities

Residential choice

$$v_{ij} = -\alpha_j p_i - \beta_j e_i$$

- Locations $i \in \{$High risk, Low risk$\}$
- Groups $j \in \{$Poor, Rich$\}$, where $\alpha_P > \alpha_R$, $\beta_P > \beta_R$

- Location utility v_{ij}
  - Housing prices p_i
  - Flood exposure $e_i = n_i - g_i$
  - Natural n_i, where $n_H > n_L$
  - Infrastructure g_i

Equilibrium prices

$$D_i(\hat{p}) = \sum_j \pi_{ij}(\hat{p}), \quad S_i = 1$$

- Demand from logit choice probabilities π_{ij}
- Supply from fixed housing stock S_i

Compensating differentials

$$\underbrace{\Delta \hat{p}}_{\hat{p}_H - \hat{p}_L} = -\bar{\gamma} \Delta e, \quad \bar{\gamma} = \frac{\beta_P + \beta_R}{\alpha_P + \alpha_R}$$

- Higher risk in H, lower price in H
- Market clears on aggregate $\bar{\gamma}$ (WTP to avoid flooding)

Sorting by income

$$c = \log\left(\frac{\pi_{HP}}{\pi_{LP}}\right), \quad \frac{\mathrm{d}\hat{c}}{\mathrm{d}\Delta e} = \alpha_P(\bar{\gamma} - \gamma_P)$$

- Sorting: concentration c of the poor in H, given exposure gap Δe
  - The rich crowd out the poor in pursuit of higher ground (Hsiao 2024)
  - Worsens inequality in exposure

- For $\gamma_j = \beta_j / \alpha_j$, sorting iff

$$\boxed{\bar{\gamma} > \gamma_P} \quad \text{and} \quad \bar{\gamma} < \gamma_R$$

Welfare by income

$$\frac{\mathrm{d}\hat{U}_j}{\mathrm{d}\Delta e} = (\bar{\gamma} - \gamma_j)\pi_{Hj}$$

- Under sorting, $\boxed{\bar{\gamma} > \gamma_P}$ and $\bar{\gamma} < \gamma_R$
  - The poor gain from exposure differences; the rich lose
  - Reduces inequality in welfare

- Market clears on aggregate $\bar{\gamma}$ (WTP)
  - For the poor, over-compensation through housing prices

Adaptation policy faces a trade-off

- Exposure-based allocation protects H $(n_H > n_L)$
  - Exposure gap $\downarrow$, aggregate losses $\downarrow$
  - But have gentrification and uniformly expensive housing
- Price-based allocation protects L $(\hat{p}_L > \hat{p}_H)$
  - Exposure gap $\uparrow$, aggregate losses $\uparrow$
  - But preserves pockets of affordable housing
- In-situ and ex-situ adaptation interact

New data on flooding in Indian cities

- Synthetic aperture radar (SAR) to measure flooding
  - Impervious to weather, works at night
  - Define flooding as deviation from norm in surface water extent
- Can incorporate more granular satellite data (Patel 2024)
  - With customization for urban environments
- Today: data for Bangalore
  - Relative Wealth Index from Meta Data for Good
  - Stormwater drains from OpenCity India

Flooding and wealth

Share of days flooded

Next steps

- More work on urban adaptation in developing countries
  - Flooding, extreme heat, pollution, sea level rise
- Adaptation policy faces trade-offs
  - In-situ vs. ex-situ
  - Equity vs. efficiency
  - Short-run vs. long-run
